

CONVERSION OF THE BRITISH CHRONOLOGY OF FLASH FLOOD EVENTS TO A CONSOLIDATED, GEOCODED DATA BASE

Motivation

The chronology of flash floods has been compiled by David Archer as a library of 17 Microsoft Word files, organised by region.

The chronology files are intuitive. Each one can easily be searched to find references to a specific place name or date.

Since the events are inherently geographical, we thought it would be neat to put them on a map. This involves finding and geocoding place names in the chronology. We also wanted to consolidate the chronology into one database and standardise the formatting of dates.

Together, these steps will help in answering questions about aggregated or distributional features of the chronology, such as “how many events were recorded in Year X” or “which places have been mentioned most often in connection with flash floods?”

Our aim was to convert the text-based format into a more structured and machine-readable data set, which could be queried by date or by geographical coordinates.

Overview of the chronology

Our analysis reveals patterns in the occurrence of flash flood event reports across Britain. **Each red disc on the map shows a place that is named in the chronology. The radius of the disc reflects how many times the place name occurs.**

There could be several influences on this pattern:

One should be the actual occurrence of flash flood events through history as a

product of weather and hydrological processes.

The map may also reflect unknown reporting biases, such as variations in what was considered noteworthy by contemporary observers. This is in part connected with changes in exposure, i.e. the presence and vulnerability of people and things that could be damaged by floods. There may also have been variation in the opportunity for reporting, such as differences over time or between regions in the number of newspapers, the number of observers/reporters, and changes in communications technology.

There may be unintentional curatorial biases reflecting differences in familiarity, opportunity or workflow during compilation of the chronology. We have confidence in the chronology, which has been compiled voluntarily by a highly experienced hydrologist. There is inevitably a level of subjectivity in the interpretation of texts; however the chronology has been well documented in peer-reviewed papers. As we will see later, our initial analysis of the consolidated data suggests that the chronology is highly informative. Ultimately, as with any interpretative work based on historical documents, there is the potential for errors of omission (events that occurred in nature but are not in the record) and errors of commission (which could occur, for example, if an event was reported at the time in an exaggerated manner).

The timeline of event reports is shown below. We have omitted five events before 1550. The number of event reports increases during the early nineteenth century, presumably reflecting the growth of newspapers and perhaps the coverage of newspaper archives. We might speculate that there could have been an increase in the exposure to flash floods driven by industrialisation, which would be consistent with the spatial pattern of place name occurrences.

It is curious that the number of event reports tailed off in the early twentieth century, with a peak in the 1920s and 30s, followed by another dip before a peak in the modern era. Perhaps the world wars meant that flash flood reports were less noteworthy in the 1910s and 1940s? Perhaps changes in exposure or infrastructure reduced their impact in the mid twentieth century? The increased occurrence of reports from the 1980s to roughly 2010 might reflect better instrumentation or digital archiving of hydrological data. The chronology alone cannot answer these questions; it is important to remember that it is a summary of historical accounts and not a time series of measurements.

Chronology source data

Each file in the original chronology contains a large table, where every row refers to an event.

The table columns are:

- A field labelled “Source” (or similar) containing free text combining the date of the event, in mixed formats, with information about the evidence sources, including newspaper titles, often with publication dates
- A field labelled “Rainfall” containing weather information in free text format
- A “Description” field containing information about the event and its impacts

In the Description column, many of the geographical names have been marked up by David Archer to help identify place names or water features. We used this markup to assist the geocoding process. David also added colour markup to highlight certain descriptive terms or the presence of hail. We have not parsed this colour highlighting.

The event tables were extracted from each Word file and converted into data frames, which were merged to give one, consolidated table.

Event dates and evidence source parsing

A set of regular expression (regex) rules were applied to split the first field of each event (row) into an event date string and a string containing the evidence source. Further regex processing was applied to standardise the dates into a common format.

Methodology for extraction of place names

Our processing concentrated on text in the Description field, and involved two main steps:

1. Named Entity Recognition (NER) to extract and tag place names
2. Geocoding to link the extracted place names with geographical coordinates

We used the “spaCy” Natural Language Processing library (<https://spacy.io/>) to parse the text.

We used the Office for National Statistics (ONS) Index of Place Names as a gazetteer to provide a definitive list of UK place names and coordinates.

Named Entity Recognition

The NER step used spaCy’s medium-sized trained model (or “pipeline”). This pipeline component extracts words or phrases that the model has inferred, from surrounding text, to be named entities. It also tags each extracted entity with a category. Further details about the tagging and categories are given in the spaCy documentation.

An example of the NER output is shown below, where the named entities are highlighted in colour, along with tags such as ‘EXCLUDE’ and ‘GPE’ (Geopolitical Entity).

The NER pipeline's tagging was not always accurate. For example, the extract above shows that the word Leyburn, which is a place name, was wrongly tagged as a person. To correct problems such as in this example, we augmented the model-based NER with two further spaCy components:

- an EntityRuler to encode logical rules that we specified to try and improve the recognition of place names and other relevant entities
- a PhraseMatcher constructed from the ONS gazetteer to find verbatim matches to valid place names

Entity Ruler

The EntityRuler was created and attached to the pipeline to match and tag ambiguous phrases before they reached the model-based NER processor.

The rules included patterns to handle the following situations:

- place names marked up as significant places in the original chronology documents by being enclosed in single <angle brackets>
- place names relating to water bodies, marked up in double <<angle brackets>>
- other references to water e.g. "River Xxxxx", "Xxxxx Beck"
- phrases with names indicating that they are street names, farms, parks, bridges, gauging stations or other infrastructure or facilities

As shown above, sometimes the NER could not distinguish correctly between people and things. An initial NER search for entities tagged by spaCy as type "PERSON" was reviewed to resolve many cases. Examples included "John Street" and "Kirk Burn". We extracted these entities into a file, manually checked them, and assigned each one an appropriate tag ("PERSON", "LOC" or "OTHER"). We then encoded literal rules in the EntityRuler to apply the tags.

Phrase Matcher

The "PhraseMatcher" finds verbatim matches to place names in the ONS gazetteer, which simplifies the later geocoding step at the cost of being sensitive to spelling mistakes or variant place name spelling or formatting.

Geocoding logic

The process of matching place names with entries in the gazetteer is not straightforward because many place names occur in multiple different locations, and there are variations in the spelling or formatting of some names. These challenges mean that geocoding is an active research area in which specialist methods have been proposed.

The structure and tagging already present in the chronology led us instead to develop a set of deterministic rules to reconcile place names extracted by the NER with locations in the ONS gazetteer. This reconciliation logic is described below.

Reconciliation of named entities and gazetteer matches

The first step was to compare named entities tagged by the rules-based NER with a verbatim search in the gazetteer. The aim of this process was to decide whether a phrase with a gazetteer match should be accepted as a place name, or rejected on the basis that the tagged phrase was (or was part of) another type of entity.

The logic applied was:

- Remove any entities that were tagged outright for exclusion by the rules-based NER pipeline (these include Road and Street names)
- Find parts of text tagged by the pattern-matching NER that overlap with parts of text matched in the gazetteer. For example, if the NER pipeline tagged the text "Victoria and Midland Hotels" with the "ORG" (organisation) type, while the same word "Victoria" (at the same position in the text) was matched against a place name Victoria in the gazetteer, then the logic should decide whether to accept the NER tag or the gazetteer match. Our rule was to prefer the NER tag and discard the gazetteer match, on the basis that for these cases the NER tags embody more information than the literal gazetteer match. Continuing the example, the rule would interpret the snippet "Victoria and Midland Hotels" as one or more organisations, rather than a place called Victoria followed by an organisation called Midland Hotels.
- Find entities tagged by the NER pipeline with an exact match of the same length in the gazetteer. For example, this would occur if the NER had tagged the word "Victoria" above (as opposed to "Victoria and Midland Hotels", which is longer than the gazetteer match "Victoria"). In such cases our rule was to prefer the gazetteer match as a precise filter. This logic was applied only where the NER tag was one of the types "PERSON", "ORG", "LOC", "GPE", "FAC" (Facility), or was a special tag to identify place names marked up within angle brackets.

Marked-up place names given priority

Some events in the chronology have long descriptions with many place names. We wanted, if possible, to thin the data so that the eventual mapping would not be too cluttered. Where an event has a mix of place names with and without angle brackets, our interpretation is that the markup highlights the most significant place names hence we retained only those names.

Assign coordinates to gazetteer matches

Following the preceding steps, there were 6426 events, each having a list of place names with matches found in the gazetteer. There were also 1721 events for which no place names or

gazetteer matches were found, and which will be tabulated separately in a future update (and can meanwhile be found in the original Word documents).

The next step was to localise the place names to find suitable geographical coordinates. This is difficult because of the many common place names and variations. For example, there are at least 10 “Burtons” dotted around the UK. If an event report mentions a place called Burton, which Burton is it?

Fortunately, the original structure of the chronology helps us resolve location ambiguities. Recall that the chronology was organised as 17 regional files. The regions were not all precisely defined, but are approximately hydrographic, reflecting the geographies of drainage basins.

The Integrated Hydrological Units (IHU) of the United Kingdom, available from the Environmental Information Data Centre (<https://eidc.ac.uk/>), helped us to define the regions more precisely. The coarsest IHU level comprises 97 Hydrometric Areas in mainland Britain plus areas for islands in UK waters and the island of Ireland. A finer level comprises the smaller Hydrometric Groups. For some of the chronology files, David Archer listed the hydrometric areas that were considered. For the other files, we created a list of associated hydrometric areas based on a subjective review of the data within the file. The Yorkshire region is one large hydrometric area, so we defined the three Yorkshire chronology regions using hydrometric groups.

Region named in original chronology documents	Hydrometric Areas [Groups]
Cumbria Eden	75, 76
Cumbria South Lakes	72, 73, 74
Cumbria West Lakes	74, 75
East Anglia	29, 30, 32, 33, 34, 35, 36, 37, 38
Lancashire	72, 71, 70, 69, 68, 67
Northeast	22, 23, 24, 25
Scotland	108, 107, 106, 105, 104, 97, 96, 95, 94, 93, 92, 91, 90, 89, 88, 87, 86, 85, 84, 83, 82, 81, 80, 79, 78, 77, 21, 20, 19, 18, 17, 16, 15, 14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1
Severn and Welsh Borders	54, 55
Southeast	37, 40, 41, 42, 101
Southwest Devon and Cornwall	49, 48, 47, 46
Southwest Somerset Wilts Dorset Avon	53, 52, 51, 50, 46, 45, 44, 43
Thames	39
Trent	28, 29, 30, 31
Wales	102, 67, 66, 65, 64, 63, 62, 61, 60, 59, 58, 57, 56, 55
Yorkshire Rye and North York Moors	26, 27 [HA025G02, HA025G03, HA025G04, HA026G01, HA026G02, HA026G03, HA027G06, HA027G09, HA027G14, HA027G15, HA027G18]
Yorkshire South	27 [HA027G02, HA027G07, HA027G16, HA027G17, HA027G12, HA027G10, HA027G03, HA027G08, HA027G04]
Yorkshire Swale	26, 27 [HA026G01, HA026G02, HA027G19, HA026G03, HA027G05, HA027G13, HA027G11, HA027G09]

We then performed a spatial join to add the hydrometric codes to the gazetteer data and filtered the gazetteer by hydrometric area or group.

The gazetteer links place names with a description field ('descnm'), which defines place name types non-exclusively such that a place name may be associated with more than one type. The 'descnm' typology enabled us to design a search rule to find the most appropriate set of coordinates for a given name. For each place name match, the rule selects the point coordinates associated with the following types in decreasing order of preference:

1. 'LOC' (locality)
2. 'BUA' (built-up area)
3. 'PAR' (civil parish)
4. 'NMD' (non-metropolitan District)
5. 'WD' (electoral Ward/Division)

So, for example, if there are coordinates (which might differ) associated with Burton as a locality and Burton as a parish, the rule will prefer the point associated with the locality.

Where a name matched more than one place in the region for a given 'descnm' type, then we took coordinates from the first match to be found in the gazetteer (subject to the region and description preference constraints).

Mapping

Jitter to avoid over-plotting

The final data set contains many points that occur in multiple event reports. Such points would plot on top of one another, obscuring all but one of the events at that location. Our intention is to make the event data easily discoverable on a map and so this behaviour is undesirable. We jittered any points with identical coordinates such that the points instead plot on a small disc of radius approximately 250m, rendering them individually visible at close zoom levels. This adjustment was applied only in the production of the map and not in the underlying data.

Jittered points all referring to the town of Kendal in north west England.

Colour coding

To help identify the events coherently and distinctively in space, we assigned every event a colour code. The colour codes were selected randomly from a colourmap such that there is a small chance that events which are close together spatially or in time will plot in the same colour.

Colour coding to identify events.

Analysis

The end goal of the chronology is to help understand flash flooding better. That is likely to involve further research, perhaps blending the chronology with other information sources. Here, we show an initial analysis of the consolidated data set, which may help to assess the qualities of the data base and to support its use.

Distribution of named entities

The plot below shows the distribution of named entities by occurrence.

The types ‘TAG_PLACE’ and ‘TAG_WATER’ refer to entities marked up in the chronology using the single and double angle brackets, “< >” and “<< >>”, respectively. The other types are tags generated by spaCy’s NER pipeline. The category ‘None found’ is for events in which no geographical entity was found. Otherwise, the counts refer to the number of occurrences of the tag throughout the chronology, including multiple occurrences of a tag within any given event.

The graph shows that the markup added by David Archer is very helpful in identifying a large number of place names. However, place names may also be found in the 16,151 entities tagged by spaCy as "PERSON", "ORG", "LOC", "GPE", "FAC". Combined with the marked-up place names, this made a total of 26,829 named entities to be processed.

Distribution of names found in gazetteer by event

The final, geocoded place names are those for which a match was found in the gazetteer. The plot below shows how the rate of gazetteer matches was distributed by event; in other words how many events had zero matches, how many had one match, etc.

The modal value is one place name per event. The distribution has a long tail, but most events matched against fewer than 10 place names in the gazetteer. We interpret this distribution as an indication of the specificity of the chronology. This may reflect

- the spatially concentrated nature of many flash floods
- the process by which we prioritised tagged place names (see above)
- a tendency in event reports to have avoided citing long lists of place names, except on rare occasions

Corrections and updates

In total, the chronology contained more than 26,000 named entities, from which we identified 4,842 unique, geocoded places. This analysis was only possible with the assistance of software. However, although we have carried out checks throughout the process, we expect that there will be errors and omissions. We anticipate finding the following types of issues:

- place names may have been missed because they do not appear in the ONS gazetteer or because of spelling mistakes or formatting errors
- the place type ('descnm') preference search may have failed to identify the right instance of a duplicated place name
- events may have appeared in two or more regions in the original chronology
- there could be some remaining ambiguity about the interpretation of accounts quoted in the chronology

We would like to find out if mistakes come to light, and to incorporate corrections in future updates of the chronology. We have created a web form

(<https://forms.office.com/e/1m6pCZV8V9>) to capture corrections or new data.

Package and data versions:

spaCy: v. 3.7.2 with NER pipeline en_core_web_md v. 3.7.1

Gazetteer: Office for National Statistics Index of Place Names as at December 2022, first published March 2023. We used the updated v. 1.1 as published May 2023. Available from <https://geoportal.statistics.gov.uk/> (last accessed October 2024).

National River Flow Archive (2014). Integrated Hydrological Units of the United Kingdom: Hydrometric Areas with Coastline NERC Environmental Information Data Centre. <https://doi.org/10.5285/1957166d-7523-44f4-b279-aa5314163237>

This note describes the 6 November 2024 release of the chronology data.

EntityRuler specification

Our NER EntityRuler is listed below in JSON format to support replication of the analysis.

```
{
  "label": "TAG_WATER",
